### Control Of Pyrotechnic Burn Rate

One mechanism, useful in adjusting pyrotech- nic output, is the control of burn rate. Burn rate determines the rate of energy release, and thus to some extent the flame temperature of a star. More directly, burn rate determines the rate of gas pro- duction from a propellant, and thus the thrust from and internal pressure within a rocket motor.

Control Of Pyrotechnic Burn Rate The combustion process of pyrotechnics was studied in order to obtain informations of the rate control parameters of burning rate. The pyrotechnics tested was made of Mg (magnesium) and TF (polyfluoroethylene). The burning rate measurements revealed that the burning rate of the Mg/TF propellants (pellet in shape) increases with increasing the weight fraction ( $\xi$ ) of Mg in the range of  $\xi > 0.33$ .

monly used. Linear burn rate can be defined as the distance the burning surface of a pyrotechnic composition advances inwardly (perpendicular to the burning surface) per unit time, and typically would be reported as inches per second (or mm/s). Even for a specific pyrotechnic material with a defined composition (including prescribed particle size and shape) there are a number of factors that will affect its burn rate.[1] Generally the most im-

To extend the burn time of the barium free formulations, it was decided to explore the use of boron carbide (B 4 C) in pyrotechnics (Table 4). Although unreactive at low temper atures, B 4 C has been shown to react with oxygen at elevated temperatures.[9] Because of its thermal behavior, it was believed that B 4 C would serve as a burn rate retardant,

The propellant burn rate is the rate at which the exposed propellant surface is consumed. (It is measured as distance normal to surface consumed in a given time.) Solid Rocket Motor Definitions: Burn Rate Coefficient: a Burn Rate Exponent: n Typical Values: 0.05-2 in/s Important: Burn rates are determined in sub-scale firing.

Burn rate is also highly dependent on pressure and temperature. Therefore, when a pyrotechnic composition is confined, its burn rate is accelerated. When the reaction is sped up drastically due to increases in pressure and temperature, such as the case with the burst charge in an aerial shell, it becomes explosive, and is known as deflagration .
