Models for the evolution of the term structure of interest rates build on stochastic calculus. We start with a crash course in stochastic calculus, which introduces Brownian motion, stochastic integration, and stochastic processes without going into mathematical details.

INTEREST RATE MODELING: A CONSCIENTIOUS CHOICE

A basic interest rate pricing model for an asset is $r = r_f + \beta(r_M - r_f)$ where r is the nominal interest rate on a given investment r_f is the risk-free return to capital r_M is the nominal interest rate on a short-term risk-free liquid bond (such as U.S. Treasury bills). β is a risk premium reflecting the length of ...

Two categories of the interest rate models, the equilibrium and no-arbitrage models, will be introduced. In addition, the forward rate models is also discussed, in which the risk factor is the instantaneous forward rate rather than the instantaneous short rate in the interest rate models.

Ch 12. Interest Rate and Credit Models

Simple models of the term structure run into the problem of “the expectations puzzle of interest rates,” in which it seems as if the yield curve fails to reflect expectations of the path of short-term interest rates. This course will resolve this puzzle by explaining how risk premia actually behave.

The formulae involved with interest rate modelling can get complicated. It is important to use an unambiguous scheme of notation that can be carried across a range of different models and at the same time is useful for calculations. Time 0 denotes the present. Times t, T, T_1, T_2, \dots , denote various future times, as does t, T, T_1, T_2, \dots .
